The infographic is titled "Why we get old" and discusses factors influencing cell aging. It includes sections on telomeres, mutations, external factors, and genetic variables. The design uses a white background with black text and small illustrations. A large brain image is on the right.

Why we get old

The aging of any organism is related to the deterioration of its cells. The more a cell deteriorates, the larger the chance it's susceptible to errors in its genetic material, which can lead to severe malfunctions and, in some cases, to cancer.

Factors that influence cell aging

1 Telomeres

On the four tips of chromosomes, there are little pieces of genetic material called telomeres. As our cells divide, they shave off a little piece of the chromosome. Every time a cell reproduces, it loses a little piece of telomeres. At first, this is not a issue, as it only affects the ends of the chromosome. However, after a cell has reproduced many times, telomeres become so short that they can't protect the genetic material that does have important functions in the organism. In essential organs like the heart, when the organ gets older, its telomeres are shorter, causing more damage.

2 Mutations

External factors like solar radiation and other factors can damage the genetic material of a cell and produce harmful mutations. These are usually repaired by the cell, but sometimes they are not able to cope.

External factors

Environmental factors like radiation and other factors can damage the genetic material of a cell and produce harmful mutations. These are usually repaired by the cell, but sometimes they are not able to cope.

What variables may help explain some people's extreme longevity

Environmental and genetic factors play a role in explaining average longevity.

According to researchers, 30% of the factors that explain how old people live are explained by genetic variation. The other 70% corresponds to environmental factors.

The study found that 30% of the factors that explain how old people live are explained by genetic variation. The other 70% corresponds to environmental factors.

These genetic variations are related to:

- Better cognitive performance
- Longer life expectancy, especially in men
- How efficient the body is at repairing damage
- Balanced diet
- Efficiency of the immune system

In the study, the researchers analyzed 10,000 individuals from 10 different countries. The results showed that the rate of aging is related to the number of genetic variants. Among the participants, 10% had more than 100 variants, while 10% had fewer than 100 variants.

Neutral tones

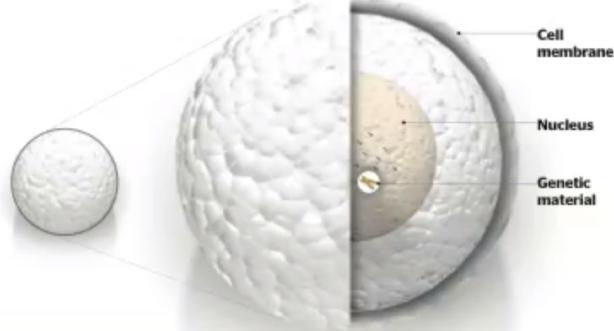

Copy color

The infographic features a color palette at the bottom. It includes a vertical column of seven squares: a light beige square, a medium beige square, a dark grey square, a black square, and a white square. To the left of the first three squares is the label "Neutral tones". To the right of the last two squares is the label "Copy color".

Types: Consistency, and following hierarchy

Why we get old

The aging of any organism is related to the deterioration of its cells. The more a cell reproduces, the larger the chances its descendants will present copying errors in their genetic material, which are one the keys to understanding aging. These errors can also lead to severe malfunctions and, in some cases, to cancer.

Factors that influence cell aging

1 Telomeres

On the four tips of chromosomes, there are little pieces of genetic material called **telomeres**. Apparently, they have no active function in the organism.

Every time a cell reproduces, it loses a little piece of telomere. At first, this is not an issue, as the cuts don't affect the body of the chromosome.

However, after having reproduced many times, telomeres become so short that further cuts can start affecting the genetic material that does have important functions in the organism.

In normal circumstances, when the organism detects that a cell has lost its telomeres and has become too old, it forces it to commit "cell suicide", also called **apoptosis**.

2 Mutations

External factors: Pollution, nicotine, solar radiation, and other factors can destroy the genetic material of a cell and provoke harmful mutations. There are mechanisms in the organism to fight them, but sometimes they are not able to cope.

Internal factors: Cells generate their own energy by means of a chemical reaction between oxygen and glucose. This process also produces toxic waste materials, called **free radicals**.

Around **5% of the oxygen** a cell receives is transformed into free radicals. In normal circumstances, the cell can control the amount of free radicals and use them in metabolic functions.

But when a cell gets older, it becomes less efficient at keeping free radicals at bay. The amount of free radicals in the organism increases, something that can lead to degenerative diseases.

What variables may help explain some people's extreme longevity

Environmental and genetic factors play a role in explaining average longevity.

According to researchers, **70%** of the factors that explain how old a person can get before dying are related to a **healthy lifestyle**. The other **30%** corresponds to genetic inheritance.

According to the studies recently released, extreme longevity (that of people reaching 95 years of age or older) is explained by genetic factors only.

Researchers identified **150 gene variations** that seem to be related to aging. Their presence in a person's genome is related to the likelihood of that person suffering from age-related diseases, such as cardiovascular problems and cancer. The more of these variations a person has, the less likely he or she is to suffer from those conditions.

These genetic variations are related to:

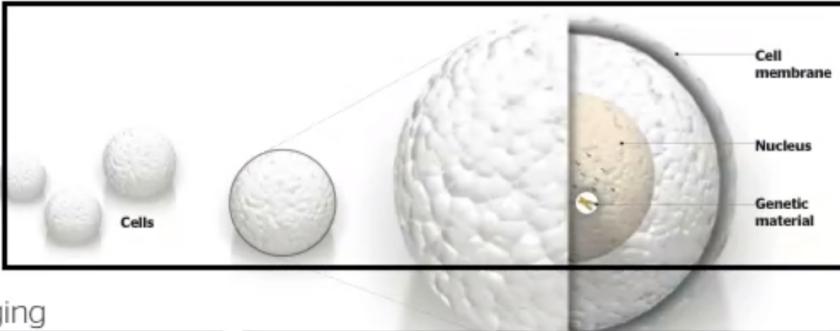

- Better cognitive performance
- Diseases like diabetes, hypertension
- How efficient the organism is at repairing cancer damage
- Bone resistance
- Efficiency of the immune system

In the study, the researchers identified 19 combinations of those 150 gene variations. The presence of one of those combinations in a person is highly related to the likelihood of surpassing 95 years of age. Among the centenarians who participated in the study, more than 90% presented one of these combinations.
